Electric Light and How it is Made To prepare an article on the "Dynamo" without the use of technical terms, diagrams r mathematics, is not an easy matter. My obj-ct, however, is to remove these stumbling blocks and prepare for the general public a clear and simple description of the appara tus used to produce the arc light such as we have in this city. I will begin with the dynamo, which is a machine for converting mechanical energy into electrical energy. It consists essentially of four parts, viz : A pully with which to apply the mechanical force, an electro-magnet with which to produce the magnetic field, an armature to rotate in the magnetic field and a set of brushes to collect the current generated in the armsture. Before proceeding further, it will be well to explain the meaning of "mag-netic fied" Every school boy is familiar with the red horse-shoe magnet which can be purchased at any hardware store. Just why the manufacturers of these toys persist in painting them red is a profound mystery. However, if iron filings be sprinkled on a piece of paper and the same be carried near a magnet they will be instantly attracted and assume a peculiar shape. The fi ings show exactly how the magnetic lines of force flow out from a magnet; the space surrounding a magnet through which these I nes of force flow is called the "magnetic field." Faraday in 1831 discovered

that if a piece of wire be moved across a magnetic field so that its movement will cut, or alter the lines of force, the lines thus cut will surround the wire and produce a feeble current of electricity in the wire. This in fluence around the wire is generally defined as magnetic whirls; these whirls can be snown by passing a wire up through a piece of card board, and sprinkling a few iros flings around the wire. When a current of electricity is passed through the wire the iron filings will immediately assume the form of concentric circles around the wire. If a feeble current is produced in a single wire by moving it through a magnetic field, it is reasonable to suppose that if a long wire be coiled upon itself many times and rapidly rotated in a magnetic field it will cut more the coiled to be received in a magnetic field it will cut more the coiled in a magnetic field it will cut more the coiled in a magnetic field it will cut more the coiled in a magnetic field it will cut more the coiled in the wire. It will thus be seen that the amount of current generated is directly proportional to the number of turns of wire rotated in the magnetic field. This arrange ment is called the armature, the wire being wound on an iron core in a direction parallel with the shaft upon which it is mounted. In the construction of an armature instead of one continuous wire, it is generally divided in a several sections. The form of sic one third of the purchase money in cash, and the residue in equal instalments at six, twelve and eighteen months from the date of sile; the deferred payments to bear interest at the rate of six per cent., and the title to be reiron filings will immediately assume the form of concentric circles around the wire. If

Have on hand GISSON'S XX, XXX, XXXX, and PURE OLD RYE. OLD CABINET and MONOGRAM WHISKIES; also BAKER'S and THOMPSON'S PURE RYE WHISKIES, to which they invite the attention of the trade.
Orders from the country for merchandise shall persony be prompt strention.

Wound on an iron core in a direction parallel with the shaft upon which it is mounted. In the construction of an armature instead of one continuous wire, it is generally divided into several sections, the ends of each section being carried to one end of the shaft and there connected to a metallic ring; this ring is divided into several sections of section being carried to one end of the shaft and there connected to a metallic ring; this ring is divided into several sections or segments, the umber of which correspond with the pumber of coils in the armature. Upon this ring, amber of which correspond with the number of coils in the armsture. Upon this ring or commutator, as it is technically termed rest the brushes, which collect the current as it is generated in the armature. It is then made to pass around the colls of the field magnet and thence to the lamps. It, instead of using the steel horse-shoe or permanent magnet, we substitute a bar of soft iron and upon this coil several layers of covered wire, we have an electro magnet which can be very highly magnetized by passing an electric current through the coil of wire. In the many acture of dynamos the mechanical construction of this magnet is so arranged that its poles lie exactly opposite each other with sufficient space between to allow the arma ure to be freely rotated on its axis.
This magnet produces the magnetic field, and is called the "field magnet." All iron contains a small amount of permanent mag-

netism. When the armature is made to revolve in the field produced by this permanent magnetism it causes a very feeble current to be generated in the armature; this feeble current passing around the full mag-net causes it to become stronger, and the stronger the field magnet becomes the more lines of force will be cut by the armature, consequently more electricity will be produced. This action continues until the field magnet becomes thoroughly magnetized, when it is then said to be saturated, and the dynamo doing its maximum work. In a good dynamo only ten per cent, of the mechanical power is lost; it is therefore seen that we have as available electrical energy ninety per cent of the power ex-pended in producing it. The arc lamp is an arrangement for bolding

two sticks of carbon in a vertical line, one above the other; the lower carbon is generally stationary, while the upper one is at-tached to a brass rod capable of being freely moved up and down. In the body of the lamp are two electro-magnets, which control the moveare two electro-magnets, which control the move-ment of the upper carbon. Through one magnet the entire current passes; this is called the lifting magnet. The other is so arranged that only a small portion of the current passes through it; this is known as the feeding magnet. When there is no current passing through the lamp the point of the upper carbon rests on that of the wer simply by force of gravitation. When the current is made to pass through the lamp the lifting magnet immediately raises the upper car-bon; at the same time the so-called "are" is form-ed between the ends of the carbons. As the car-

bon; at the same time the so-called "are" is formed between the ends of the carbons. As the carbons burn the space between them is gradually increased, until at length the are would be broken were it not for the feeding magnet, which, when the are has reached a predetermined length causes the upper carbon to descend a little This burning and feeding continues as long as a current flows through the lamp. Some lamps are provided with two sets of carbons so arranged that when one set burns out the other by an automatic device is awitched in circuit. In practice there are several other mechanical detais, but those mentioned are the principal ones.
